Dual-Ton DT LT $\rightarrow$ DT LT LT
 $\hookrightarrow$ pair almost invariant in
 time
 $\hookrightarrow$ two decomposition tones

It's like if you had a complex wave
 and a varying part

It's like Fourier

To map with signal & filter to
 the signal we use Hilbert transform
 (it's a filter of type pass
 all) to shift it by 90°

$$v[n] = \begin{cases} \frac{2}{n\pi} & , n \text{ odd} \\ 0 & , n \text{ even} \end{cases}$$

↑ the filter
pass all

At the end you join the results from both trees into another composition that is much a way that they are the whole
($\sqrt{x^2 + y^2}$)

it makes the description in
asymptotically stationary (invariant)
without removing the sig as S-DWT

Ensemble $\rightarrow$ 2D

- $\hookrightarrow$ search for cues
- $\hookrightarrow$ matched wavelet / tailored
- $\hookrightarrow$ pattern matching
- $\hookrightarrow$ extract features / patterns
 - $\hookrightarrow$ different size and angle

Domain DTWT $\rightarrow$ DDTWT

- $\hookrightarrow$ optimized for denoising acoustic signals
- $\hookrightarrow$ usually to domain you modify the signal before entering in DDTWT before modifying you adjust the value by a factor K that relates to the human auditory system. later we apply $1/K$

Matched wavelet $\rightarrow$ filter matched to a specific signal

- $\hookrightarrow$ we map the signal into a plane Time-Frequency-Fourier

↳ it holds for most
data

Lifting Scheme → a way to separate
DFT into a series of
elementary operations called
lifting steps

If you compare the wave packet you
with artifacts increasing the energy
